

INLAND STRANDED OIL HABITAT FACT SHEET FOR RESPONSE: Deep Marsh Shrub Habitat

I. Habitat

The Deep Marsh Shrub Habitat is found in or around lakes, ponds, backwaters, or shorelines that are >25% vegetated with semipermanently flooded shrubby vegetation. Common vegetation types include buttonbush (*Cephalanthus*), and swamp loosestrife (*Decodon*). This general class may have inclusions of submersed, nonrooted-floating aquatics, rooted-floating aquatics, or emergent vegetation. This habitat is more common in southern aquatic systems.

Decodon spp.

II. Sensitivity to Oil Spills

The deep marsh shrub habitat is highly sensitive to oil spills. This habitat is valuable to a variety of birds, amphibian, reptile, and mammal species as well as micro and macro invertebrates, many of which are extremely sensitive to chemical exposure. During normal water levels, oil would be less likely to penetrate water-saturated soils; during floods, oil could be deposited in areas that dry out after the flood, and penetrate the loose, organic-rich surface soils. Light refined oils with high amounts of water-soluble fractions can cause acute mortality to animals and plants. Heavier oils tend to coat vegetation, which may survive if oil coats only the stems or if the roots are unaffected. It is difficult for more viscous oils to penetrate densely vegetated areas.

Deep Marsh Shrub Habitat

III. Sensitivity to Response Methods

The following text describes potential adverse impacts to this habitat resulting from various oil spill response methods and provides recommendations to reduce impact when these methods are implemented. This is not intended to preclude the use of any particular methods, but rather to aid responders in balancing the need to remove oil with the possible adverse effects of removal. More detail about the response methods themselves can be found in the [Inland Response Tactics Manual](#).

Least Adverse Habitat Impacts

Exclusion or Deflection Booming

- Boom can be used to exclude or deflect the spill away from sensitive resources.
- Effectiveness is increased by positioning boom at appropriate angles for the current speed.

Natural Attenuation

- Least impact for small to moderate spills and lighter oils; avoids damage often associated with cleanup activities.
- Some cleanup may be warranted where large numbers of wildlife are likely to become oiled during wetland use.
- Seeding or planting may be used to assist in oil degradation.

Sorbents

- Care is necessary during placement and recovery to minimize disturbance of substrate and vegetation
- Overuse generates excess waste.
- Forcing contact between pads and the oiled soil drives the oil deeper into the soil.
- Appropriate approval required for chemical additives to sorbents.

Flooding

- Erosion of substrate and vegetation may occur.
- Can be used selectively to remove localized heavy oiling.
- Local topography may limit the ability to control where the water and released oil flow and effectiveness of recovery.
- Boom or other methods of trapping and containment are used to collect the oil for removal.
- Effectiveness increases with lighter oils.

Low-Pressure, Ambient-Water Flushing

- If water pressures are too high, the substrate and vegetation may be disturbed.
- Effectiveness increases with lighter oils.

Solidifiers

- Use likely to increase adherence to vegetation and slow weathering/removal rates of residual oil.
- Most effective on lighter oils, which have low viscosity and allow the product to mix into the oil.
- Appropriate approval required.

Some Adverse Habitat Impact

In-Situ Burning

- May be one of the least physically damaging means of heavy oil removal.
- Presence of a water layer on marsh surface can protect roots.
- Time of year (vegetation growth stage) is important consideration.
- Heavy ends will remain unburned and will need to be recovered.
- Requires RRT approval and a state air permit.

Vacuum

- Can be effective in removal of pooled oil from the marsh surface.
- Trampling of vegetation and substrate can be limited by placing boards on the surface and limiting traffic.

Debris/Vegetation Removal

- The removal of heavily oiled and mobile debris may reduce the tracking of oil off-site and contamination of wildlife
- May be required in areas used by wildlife. Grass plants are damaged by oil at the root structure, removal of stained or oiled vegetation is to protect users of the habitat.
- Most appropriate for oils that form a thick, sticky coating on the vegetation, such as medium and heavy oils.
- Recovery of the vegetation due to both oil impact and physical destruction by cleanup crews may be reduced by avoiding excessive cutting/removal, controlling access routes, using boards placed on surface, or conducting operations from boats.

Hand Tool Oil Removal/Cleaning

- Used where persistent oil occurs in heavy amounts and where sensitive resources using the wetlands are likely to be oiled.
- Mixing of oil and trampling of vegetation may be reduced by controlling access routes, using boards placed on surface, or conducting operations from boats.
- This includes removal of surface soil contamination not gross digging.

Most Adverse Habitat Impact

Light Equipment Oil Removal

- Use equipment such as swamp buggies or light equipment on pontoons.
- Damage to vegetation and substrate may be reduced by controlling access routes, using pontoons or mats, or using a helicopter to bring in equipment.

Sediment Removal

- Vacuum/dredge sediments and dewater using geotube/settling tank. Treat the water and dispose of sediment.
- Excavate the sediment. Dewater the area before excavation.
- The hydrology may change and it may be difficult to restore the plant community that existed prior to the spill incident.
- Permits will be required for sediment removal and for water discharge.
- May be difficult to keep excavation dewatered.
